# Vote Weight Disparity with Endogenous Information: A Note* 

Minoru Kitahara ${ }^{\dagger}$<br>Institute of Social Science, University of Tokyo<br>JSPS Research Fellow

May 19, 2006

#### Abstract

A large society is confronted with a dichotomous choice. There are predetermined weights with which the members' votes are summed up and the society chooses the alternative that wins the plurality. The members' information about the alternatives are endogenous: they invest some efforts before making their votes, and the levels of the investments determine the accuracies of their votes. We find that removing off the existing vote weight disparity could deteriorate the society's performance, but whether it would occur or not can be figured out by just checking the sign of some covariances.

JEL classification numbers: D72, D82
Keywords: vote weight disparity, endogenous information

[^0]
## 1 Introduction

In collective decision processes, there are sometimes essential vote weight disparities among members (maybe due to historical reasons). Once the disparity is recognized as unignorably large, the correction becomes public concern. The correction would remedy inequity among members. However, once considering (i) the role of the collective decision process for aggregating dispersed information among members and (ii) the existence of their efforts to gather such information (or cast their votes more carefully), another aspect arises: it would also change their incentives to make such efforts, which might result in the worse performance of the collective decision.

To approach this aspect, we develop an election model with vote weight disparities and accuracy improvement costs, and investigate its asymptotic properties. (Theorem.) We find that (i) the performance could be damaged by removing off the existing disparity, but (ii) whether it would happen or not can be simply figured out by just checking the sign of some covariances. (Corollaries 1 and 2.)

The next section presents the model, and the results and discussions are in Section 3. The proof of Theorem is in Appendix.

## 2 Model

There is a set of voters, $N_{n}=\left\{1,2, \ldots,\left|N_{n}\right|\right\}$, the size of which is an odd number and $\lim _{n \rightarrow \infty}\left|N_{n}\right|=\infty$. The strategy of each voter $i \in N_{n}$ is the accuracy of his vote, $q_{i} \in[1 / 2,1]$, for which he incurs the investment costs of $C_{i}\left(q_{i}\right) . C_{i}(q)$ is strictly increasing, strictly convex and twice continuously differentiable in $q$, and $C(1 / 2)=0$. If the society succeeds in adopting the right policy, he receives the utility $r_{i}$. Otherwise, he receives 0 .

The policy is chosen between two (symmetric) alternatives by majority vote, where the vote of each voter $i$ is multiplied by an integer $m_{i}$ : i.e., the alternative that acquires strictly more than $\sum_{i} m_{i} / 2$ votes wins. For simplicity, denote $M_{n} \equiv \sum_{i} m_{i}$. To avoid tie-breaking, we assume that $M_{n}$ is an odd number.

We assume that the accuracies of voters are independent: let $\left\{x_{i}\left(q_{i}\right)\right\}_{i \in N_{n}}$ be independent random variables such that

$$
x_{i}\left(q_{i}\right)= \begin{cases}1 & \text { with probability } q_{i}, \text { and }  \tag{1}\\ 0 & \text { with probability } 1-q_{i}\end{cases}
$$

$x_{i}=1$ corresponds to the event that a voter $i$ votes for the right alternative, and $x_{i}=0$, for the wrong
one. ${ }^{1}$ Then, the probability that the right alternative is chosen is

$$
\begin{equation*}
\operatorname{Pr}\left(\sum_{i} m_{i} x_{i}\left(q_{i}\right)>\frac{M_{n}}{2}\right) \tag{2}
\end{equation*}
$$

In summary, given strategies $\left\{q_{j}\right\}_{j \in N_{n}}$, the payoff to each voter $i$ is

$$
\begin{equation*}
r_{i} \operatorname{Pr}\left(\sum_{j} m_{j} x_{j}\left(q_{j}\right)>\frac{M_{n}}{2}\right)-C_{i}\left(q_{i}\right) \tag{3}
\end{equation*}
$$

Voters are classified in finite $(K<\infty)$ subgroups, $\left\{N_{n}^{k}\right\}_{k=1, \ldots, K}$. If $i \in N_{n}^{k}$, then $\left(r_{i}, m_{i}, C_{i}\right)=$ $\left(r_{k}, m_{k}, C_{k}\right)$. Denote $\alpha_{n}^{k} \equiv\left|N_{n}^{k}\right| /\left|N_{n}\right|$. Let each subgroup account for positive share: $\alpha_{k} \equiv \lim _{n \rightarrow \infty} \alpha_{n}^{k}>$ 0 for all $k$. To make sure some smoothness, we assume that a positive (but arbitrarily small) fraction of voters have a unit vote: $m_{k}=1$ for some $k .^{2}$

We focus on symmetric pure Nash equilibria: i.e., an equilibrium is characterized by $\left\{q_{n}^{k}\right\}_{k=1, \ldots, K}$ such that for all $k$ and for all $i \in N_{n}^{k}$,

$$
\begin{equation*}
q_{n}^{k}=q_{i} \in \arg \max _{q_{i}} r_{i} \operatorname{Pr}\left(\sum_{j} m_{j} x_{j}\left(q_{j}\right)>\frac{M_{n}}{2}\right)-C_{i}\left(q_{i}\right) \tag{4}
\end{equation*}
$$

The probability in the equilibrium that the right alternative is chosen is

$$
\begin{equation*}
\operatorname{Pr}\left(\sum_{k} \sum_{i \in N_{n}^{k}} m_{k} x_{i}\left(q_{n}^{k}\right)>\frac{M_{n}}{2}\right) \tag{5}
\end{equation*}
$$

The probability in the equilibrium that the right alternative wins the majority in a subgroup $k$ is

$$
\begin{equation*}
\operatorname{Pr}\left(\sum_{i \in N_{n}^{k}} x_{i}\left(q_{n}^{k}\right)>\frac{\left|N_{n}^{k}\right|}{2}\right) \tag{6}
\end{equation*}
$$

For the cases of $K=1$, Martinelli (2004) shows that if $C_{1}^{\prime}(1 / 2)=0$ and $0<C_{1}^{\prime \prime}(1 / 2)<\infty$, then (5) converges to $\Phi(d)$ as $n$ grows, where $\Phi$ is the cumulative distribution function of $N(0,1)$, and $d$ solves

$$
\begin{equation*}
\frac{\phi(d)}{d}=\frac{C_{1}^{\prime \prime}(1 / 2)}{4} \tag{7}
\end{equation*}
$$

[^1]where $\phi$ is the probability density function. Note that for any $d \in(0, \infty)$, there exists $C_{1}^{\prime \prime}(1 / 2) \in$ $(0, \infty)$ that satisfies (7). Moreover, as we can see in Martinelli (2004) (or (19) in Appendix here), the requirement of $C_{1}^{\prime}(1 / 2)=0$ is equivalent to just requiring that voters do not give up positive investments as long as there remains a possibility of affecting the outcome. Thus, we can interpret any probability of the right choice (not worse than a fair coin toss) in reality as a limit behavior of the model here with no vote weight disparity and an identical cost function that is not so implausible. We find in the next section that such interpretations are also possible with any other disparities.

## 3 Results and Discussions

For simplicity, denote average values as $A[y] \equiv \sum_{k} \alpha_{k} y_{k}$.
Theorem. Suppose that $C_{k}^{\prime}(1 / 2)=0$ and $0<C_{k}^{\prime \prime}(1 / 2)<\infty$ for all $k$. Then, as $n$ grows, (5) converges to $\Phi(d)$ where $d$ solves

$$
\begin{equation*}
\frac{\phi(d)}{d}=\frac{1}{4} \frac{A\left[m^{2}\right]}{A\left[r m^{2} / C^{\prime \prime}(1 / 2)\right]} \tag{8}
\end{equation*}
$$

Moreover, for all $k$, ( 6 ) converges to $\Phi\left(\sqrt{\alpha_{k}} e_{k}\right)$ where $e_{k}$ solves

$$
\begin{equation*}
e_{k}=\frac{r_{k} m_{k}}{C_{k}^{\prime \prime}(1 / 2)} \frac{\sqrt{A\left[m^{2}\right]}}{A\left[r m^{2} / C^{\prime \prime}(1 / 2)\right]} d \tag{9}
\end{equation*}
$$

Thus, any probability of the right choice with any distribution of voters' utilities and vote weights can be justified. Moreover, if we accept the ability indifference (i.e., $C_{k}=\bar{C}$ for all $k$ ), then we can predict the probability with no disparity, and simply by just checking the sign of the covariance of utilities and squared vote weights, figure out whether the performance would deteriorate or not. We summarize these implications below.

Corollary 1. Consider any $\left\{\left(\alpha_{k}, r_{k}, \hat{m}_{k}\right)\right\}$ and $P \in(1 / 2,1)$. Then, there exists $\bar{C}$ with $\bar{C}^{\prime}(1 / 2)=0$ and $0<\bar{C}^{\prime \prime}(1 / 2)<\infty$ such that: if $\left\{m_{k}\right\}=\left\{\hat{m}_{k}\right\}$ and $C_{k}=\bar{C}$ for all $k$, then (5) converges to $P$. Moreover, for any such $\bar{C}$ : if $m_{k}=1$ for all $k$, then (5) converges to $P_{0}=\Phi\left(d_{0}\right)$ where $d_{0}$ solves

$$
\begin{equation*}
\frac{\phi\left(d_{0}\right)}{d_{0}}=\frac{A\left[r \hat{m}^{2}\right]}{A[r] A\left[\hat{m}^{2}\right]} \frac{\phi(d)}{d} \tag{10}
\end{equation*}
$$

where $d$ solves $\Phi(d)=P$. (10) implies that $P_{0}<P$ if and only if

$$
\begin{equation*}
\operatorname{Cov}\left(r, \hat{m}^{2}\right)>0 \tag{11}
\end{equation*}
$$

It is sometimes difficult to know about voters' utilities as well as their abilities. However, present behaviors of voters under the existing disparity may provide us some information about them. The following corollary states that learning how often the right alternative wins the majority in each subgroup under the existing disparity, $\left\{P_{k}\right\}$, is enough to predict the performance with no disparity, even though we do not impose the restriction of identical abilities there.

Corollary 2. Consider any $\left\{\left(\alpha_{k}, \hat{m}_{k}\right)\right\}$ and $\left\{P_{k}\right\}$ with $1 / 2<P_{k}<1$ for all $k$. Then, there exists $\left\{C_{k}\right\}$ with $C_{k}^{\prime}(1 / 2)=0$ and $0<C_{k}^{\prime \prime}(1 / 2)<\infty$ for all $k$ and $\left\{r_{k}\right\}$ such that: if $\left\{m_{k}\right\}=\left\{\hat{m}_{k}\right\}$, then (6) converges to $P_{k}$ for all $k$. Moreover, for any such $\left\{C_{k}\right\}$ and $\left\{r_{k}\right\}$ : (i) if $\left\{m_{k}\right\}=\left\{\hat{m}_{k}\right\}$, then (5) converges to $P=\Phi(d)$ where

$$
\begin{equation*}
d=\frac{A[\hat{m} e]}{\sqrt{A\left[\hat{m}^{2}\right]}} \tag{12}
\end{equation*}
$$

where $e_{k}$ solves

$$
\begin{equation*}
P_{k}=\Phi\left(\sqrt{\alpha_{k}} e_{k}\right) \tag{13}
\end{equation*}
$$

for all $k$, and (ii) if $m_{k}=1$ for all $k$, then (5) converges to $P_{0}=\Phi\left(d_{0}\right)$ where $d_{0}$ solves

$$
\begin{equation*}
\frac{\phi\left(d_{0}\right)}{d_{0}}=\frac{A[\hat{m} e]}{A[e / \hat{m}] A\left[\hat{m}^{2}\right]} \frac{\phi(d)}{d} . \tag{14}
\end{equation*}
$$

(14) implies that $P_{0}<P$ if and only if

$$
\begin{equation*}
\operatorname{Cov}\left(e / \hat{m}, \hat{m}^{2}\right)>0 . \tag{15}
\end{equation*}
$$

Finally, we briefly discuss how biased the prediction will be if one ignores the endogeneity. ${ }^{3}$ It is equivalent to regarding $\left\{e_{k}\right\}$ as given exogenously: he expects that the probability of the right choice would become $\hat{P}_{0}=\Phi\left(\hat{d}_{0}\right)$ under no disparity from $P=\Phi(d)$ with $d$ in (12) under the existing disparity, where

$$
\begin{equation*}
\hat{d}_{0}=\frac{A[1 e]}{\sqrt{A\left[1^{2}\right]}}=A[e] . \tag{16}
\end{equation*}
$$

Thus, he concludes that the performance would not be damaged if and only if

$$
\begin{equation*}
\hat{d}_{0}=A[e] \geq \frac{A[\hat{m} e]}{\sqrt{A\left[\hat{m}^{2}\right]}}=d . \tag{17}
\end{equation*}
$$

[^2]Then, can it happen that he concludes that the performance would deteriorate by removing existing disparity away though actually it would not? Surely it can. Consider cases with $e_{k}=a \hat{m}_{k}^{b}$ for all $k$. If $b<1$, then $\operatorname{Cov}\left(e / \hat{m}, \hat{m}^{2}\right)<0$, and hence $P_{0}>P$. However, for $b=1$,

$$
\begin{equation*}
\frac{A[\hat{m} e]}{\sqrt{A\left[\hat{m}^{2}\right]}}=a \sqrt{A\left[\hat{m}^{2}\right]}>a A[\hat{m}]=A[e] . \tag{18}
\end{equation*}
$$

Thus, $\hat{P}_{0}<P<P_{0}$ everywhere within an interval $b \in(\underline{b}, 1)$ for some $\underline{b}<1$. In other words, the prediction ignoring the endogeneity is biased in favor of status quo vote weight disparity.

## Appendix

Proof of Theorem: For simplicity, denote $S_{n} \equiv \sum_{k} \sum_{i \in N_{n}^{k}} m_{k} x_{i}\left(q_{n}^{k}\right)$ and $S_{n}^{i} \equiv S_{n}-m_{k} x_{i}\left(q_{n}^{k}\right)$ for $i \in N_{n}^{k}$. Let $E_{n} \equiv E\left[S_{n}\right]=\sum_{k}\left|N_{n}^{k}\right| m_{k} q_{n}^{k}$ and $V_{n} \equiv \operatorname{Var}\left(S_{n}\right)=\sum_{k}\left|N_{n}^{k}\right| m_{k}^{2} q_{n}^{k}\left(1-q_{n}^{k}\right)$. Define $d_{n}$ as

$$
d_{n} \equiv \frac{E_{n}-M_{n} / 2}{\sqrt{V_{n}}} .
$$

Then, by the central limit theorem, ${ }^{4}(5)$ converges to $\Phi(d)$ if $\lim _{n \rightarrow \infty} d_{n}=d$.
The first order conditions of (4) yield ${ }^{5}$

$$
\begin{equation*}
r_{k} \sum_{m=1}^{m_{k}} \operatorname{Pr}\left(S_{n}^{i}=\frac{M_{n}+1}{2}-m\right)=C_{k}^{\prime}\left(q_{n}^{k}\right) \tag{19}
\end{equation*}
$$

For simplicity, let $P_{n}^{k}(m) \equiv \operatorname{Pr}\left(S_{n}^{i}=\left(M_{n}+1\right) / 2-m\right)$ for some (and hence for all) $i \in N_{n}^{k}$. Then, rearranging (19) yields

$$
\begin{equation*}
\frac{\sqrt{V_{n}} \sum_{m=1}^{m_{k}} P_{n}^{k}(m) / m_{k}}{\phi\left(d_{n}\right)} \frac{\phi\left(d_{n}\right)}{d_{n}}=\frac{C_{k}^{\prime}\left(q_{n}^{k}\right) /\left(r_{k} m_{k}\right)}{E_{n} / M_{n}-1 / 2} \frac{V_{n}}{M_{n}} \tag{20}
\end{equation*}
$$

First, we show that $\limsup _{n \rightarrow \infty} d_{n}<\infty$. Suppose, on the contrary, that along some subsequence, $\lim _{n \rightarrow \infty} d_{n}=\infty$. If $\lim _{n \rightarrow \infty} d_{n} /\left|N_{n}\right|^{1 / 2}>0$, then since $\lim _{n \rightarrow \infty} \sqrt{V_{n}} / d_{n}<\infty$, the LHS of (20) converges to 0 . Otherwise, note that by (19), $\max _{k}\left|q_{n}^{k}-1 / 2\right| \rightarrow 0$. Thus, $V_{n} /\left|N_{n}\right| \rightarrow \sum_{k} \alpha_{k} m_{k}^{2} / 4>0$. Therefore, since $m_{k}=1$ for some $k$, by the local limit theorem, ${ }^{6}$

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \frac{\sqrt{V_{n}} P_{n}^{k}(m)}{\phi\left(d_{n}\right)}=1 \text { for all } k, \text { for } 1 \leq m \leq m_{k} \tag{21}
\end{equation*}
$$

Thus, the first term of the LHS converges to 1 , and hence the LHS to 0 again. However, let $k(n) \in$ $\arg \max _{k} q_{n}^{k}$. Then,

$$
\frac{C_{k(n)}^{\prime}\left(q_{n}^{k(n)}\right)}{E_{n} / M_{n}-1 / 2} \geq \frac{C_{k(n)}^{\prime}\left(q_{n}^{k(n)}\right)}{q_{n}^{k(n)}-1 / 2} \geq \min _{k} \frac{C_{k}^{\prime}\left(q_{n}^{k}\right)}{q_{n}^{k}-1 / 2} \rightarrow \min _{k} C_{k}^{\prime \prime}(1 / 2)>0 \text { as } n \rightarrow \infty .
$$

Thus, contradictorily, the RHS for $k(n)$ does not converge to 0 .
Therefore, $\lim \sup _{n \rightarrow \infty} d_{n}<\infty$ holds. Then, by the local limit theorem as above, (21) holds again. Thus, for all $k, k^{\prime}$,

$$
\lim _{n \rightarrow \infty} \frac{\sum_{m=1}^{m_{k}} P_{n}^{k}(m) / m_{k}}{\sum_{m^{\prime}=1}^{m_{k^{\prime}}} P_{n}^{k^{\prime}}\left(m^{\prime}\right) / m_{k^{\prime}}}=1
$$

[^3]which implies, by (19),
\[

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \frac{C_{k}^{\prime}\left(q_{n}^{k}\right) /\left(r_{k} m_{k}\right)}{C_{k^{\prime}}^{\prime}\left(q_{n}^{k^{\prime}}\right) /\left(r_{k^{\prime}} m_{k^{\prime}}\right)}=1 . \tag{22}
\end{equation*}
$$

\]

Therefore,

$$
\begin{align*}
\frac{C_{k}^{\prime}\left(q_{n}^{k}\right) /\left(r_{k} m_{k}\right)}{E_{n} / M_{n}-1 / 2} & =\frac{1}{\left.\sum_{k^{\prime}} \alpha_{n}^{k^{\prime}} r_{k^{\prime}} m_{k^{\prime}}^{2} C_{k^{\prime}}^{\prime}\left(q_{n}^{k^{\prime}}\right)\right) / r_{k^{\prime}} m_{k^{\prime}}} \frac{\sum_{k^{\prime}}^{k^{\prime}}-1 / 2}{\sum_{k^{\prime \prime}} \alpha_{n}^{k^{\prime \prime}} m_{k^{\prime \prime}}} \frac{C_{k}^{\prime}\left(q_{n}^{k}\right) /\left(r_{k} m_{k}\right)}{C_{k^{\prime}}^{\prime \prime}\left(q_{n}^{k^{\prime}}\right)} \\
& \rightarrow \frac{\sum_{k^{\prime}} \alpha_{k^{\prime}} m_{k^{\prime}}}{\sum_{k} \alpha_{k} r_{k} m_{k}^{2} / C_{k}^{\prime \prime}(1 / 2)} \text { as } n \rightarrow \infty \tag{23}
\end{align*}
$$

Since $\lim _{n \rightarrow \infty} V_{n} / M_{n}=(1 / 4)\left(\left(\sum_{k} \alpha_{k} m_{k}^{2}\right) /\left(\sum_{k^{\prime}} \alpha_{k^{\prime}} m_{k^{\prime}}\right)\right)$, (20), (21) and (23) imply that $d$ must solve (8).

Define $d_{n}^{k}$ as

$$
d_{n}^{k} \equiv \frac{\left|N_{n}^{k}\right|\left(q_{n}^{k}-1 / 2\right)}{\sqrt{\left|N_{n}^{k}\right| q_{n}^{k}\left(1-q_{n}^{k}\right)}} .
$$

Then, since

$$
\begin{equation*}
d_{n}=\sum_{k} m_{k} d_{n}^{k} \sqrt{\frac{\left|N_{n}^{k}\right| q_{n}^{k}\left(1-q_{n}^{k}\right)}{\sum_{k^{\prime}}\left|N_{n}^{k^{\prime}}\right| m_{k^{\prime}}^{2} q_{n}^{k^{\prime}}\left(1-q_{n}^{k^{\prime}}\right)}}, \tag{24}
\end{equation*}
$$

(22) and the central limit theorem again imply (9).
